1. (35%)
- (a) (3%) Write down the definition of the fanning friction factor for flow in conduits.
- (b) (8%) Assume that a Newtonian fluid with a constant density ρ and constant viscosity μ flows at an unknown rate u_1 through a horizontal steel pipe having a length L and diameter D ; please derive a formula that gives the fanning friction factor in terms of ρ , μ , L , D , and ΔP under a pressure difference ΔP . Also derive the formula for the friction factor as a function of the Reynolds number in laminar flow.
- (c) (8%) What pressure difference is required to cause the liquid (having a density of 875 kg/m^3 and $\mu=1.13 \times 10^{-3} \text{ Pa}\cdot\text{s}$) to flow at a volumetric rate $1.066 \times 10^{-6} \text{ m}^3/\text{s}$ in a horizontal, smooth, circular tube with an inside diameter of $2.22 \times 10^{-3} \text{ m}$ and a length 0.317 m ?
- (d) (8%) The Newtonian fluid is flowing at an unknown velocity u_1 through a horizontal pipe of cross-sectional area A_1 at a pressure p_1 , and then it passes to a section of the pipe in which the area is reduced gradually to A_2 , and the pressure is p_2 . Assuming no friction losses, calculate the velocities u_1 and u_2 if the pressure difference (p_1-p_2) is measured.
- (e) (8%) A mechanical-energy loss should be considered, however, when the fluid flows from a small pipe to a large pipe through an abrupt expansion. Calculate the velocities u_1 and u_2 if the pressure difference (p_1-p_2) is measured.
2. (20%)
- A heated sphere of radius R is suspended in a large, motionless body of fluid. It is desired to study the heat conduction in the fluid surrounding the sphere in the absence of convection. The surface temperature of sphere is T_R , the temperature of infinite fluid is T_∞ , and k is the thermal conductivity of fluid.
- (a) (12%) Determine the temperature distribution of fluid.
- (b) (5%) Find the relationship for predicting the Nusselt number.
- (c) (3%) In what respect are the Biot number and the Nusselt number different?
3. (10%)
- The empirical equation of the friction factor for turbulent flow in smooth tubes is
- $$f/2 = 0.023 \text{Re}^{-0.2}$$
- The Colburn j factor for heat transfer is defined as
- $$j_H = (h / \rho v c_p) \text{Pr}^{2/3}$$
- and the Colburn j factor for mass transfer is defined as
- $$j_D = (k_c / v) \text{Sc}^{2/3}$$
- Here v is the characteristic velocity. Find the equations for predicting the Nusselt number and the Sherwood number.

4. (35%)

Consider the timed drug-release pill illustrated below.

The pill is ingested into the stomach. The pill is a slab, 0.36 cm per side, that has an array of 16 cylindrical pores in it. Each pore is 0.4 mm in diameter and 2.0 mm deep. Pure solid drug A is loaded into each pore to a depth of 1.2 mm, which provides a total initial drug loading of 2.65 mg in all of the pores. The density of the solid drug A is 1.10 g/cm^3 . The drug dissolves into the fluid inside the stomach, which approximates the properties of water (component B). The maximum solubility of drug A in water is $2.0 \times 10^{-5} \text{ cm}^2/\text{s}$ at body temperature of 37°C . The molecular weight of the drug is 120 g/mol.

- (10%) Starting with the general differential equation for mass transfer and Fick's flux equation, develop a simple model, in final integrated form, for predicting the flux of the drug from one pore. You may assume that the diffusion process is pseudo-steady state, the stomach fluid serves as an infinite sink for the drug so that $c_A = 0$, and the drug does not chemically degrade inside the pore.
- (10%) From your model, determine the total transfer rate of the drug from the whole pill, W_A , to the body when each 0.2 cm pore is filled to a depth of 0.12 cm with solid drug.
- (15%) How many hours will it take for all of the drug to be released?
